## **ACKNOWLEDGMENTS**

Appreciation is expressed to the cooperators that provided their land, equipment and time in assisting with prepping, planting, managing and harvesting of these plots throughout the year. All cooperators are listed in Table 1. We would also like to extend our appreciation to the Cotton Seed Companies for providing seed and operating funds for these trials and Cotton Incorporated through Core Funds and the Texas State Support Committee for their partial support of these trials. Lastly we express our appreciation to all of the technicians, scouts, and support staff that assisted in the trials.

## **2012 HIGHLIGHTS**

Variety selection is the most important decision made during the year. Unlike herbicide or insecticide decisions that can be changed during the season to address specific conditions and pests, variety selection is made only once, and variety selection dictates the management of a field for the entire season. Attention should be focused on agronomic characteristics such as yield, maturity, and fiber quality when selecting varieties. Figure 1 outlines the Best Management Practices for variety selection. Table 4 provides a summary of agronomic characteristics for the 39 varieties and experimental varieties tested in the San Angelo Uniform Irrigated Small Plot Variety Trial (M. Block, cooperator).

Texas producers planted 6.6 million acres of cotton in 2012, 0.5 million less than in 2011. From the latest data available, transgenic varieties accounted for 99% of the states acreage in 2012, which is up from 86% in 2011. Several transgenic traits are available in different cotton varieties providing herbicide and insect resistance. In Extension Districts 6 and 7, glyphosate resistant varieties are planted on essentially all acreage, but varieties with both glyphosate and insect resistant traits are not planted on all dryland acreage. According to the USDA-Agricultural Marketing Service “Cotton Varieties Planted 2012 Crop” survey, the estimated percentage of upland cotton planted to specific brands in Texas are as follows: Alltex had 8.6%, Americot/NexGen had 18.6%, Bayer CropScience – FiberMax had 40%, Bayer CropScience – Stoneville had 2.3%, Croplan Genetics had 0.3%, Delta Pine had 19%, Dyna-Grow had 2.4%, and Phytogen had 8.4%.

To assist Texas cotton producers in remaining competitive in the Southern Rolling Plains and Permian Basin of Texas, the Texas A&M AgriLife Extension Service Agronomy program has been conducting research and demonstration variety trials (Fig. 2). This approach provides a good foundation of information that can be utilized to assist the variety selection process.

Thirteen large plot unreplicated demonstration, two small plot replicated research, and one large plot replicated research trials were planted in 2012. One demonstration trial in Martin County was lost due to drought. Harvested trials are summarized by location in Table 1.

Table 1 provides a list of planting and harvest dates, row spacing and plot area for each location, and indicated irrigated or dryland. Tables 2 and 3 show numerical rankings based upon gross revenue and lint yield for the variety trials across all locations separated into Extension District. Variety trials were planted in the following Extension District 7 Counties: Jones (Table 5), Nolan (Table 6), Fisher (Table 7), Tom Green (Tables 8-11). Variety trials were planted in the following Extension District 6 Counties: Howard (Tables 12 & 13), Upton (Table 14), Glasscock (Tables 15-19), and Martin (Not Harvested). All harvested locations had cotton grab samples that were ginned in Lubbock with the research gin with one lint cleaner. Fiber quality was determined by sending one or more samples per variety to the Texas Tech Biopolymer Laboratory for HVI analysis.

For unreplicated trials averages are calculated and values in a particular column that are above average are shaded. For replicated trials or trials with subsamples, statistical results are presented. The statistical analysis quantifies the variability of the test site conditions, such as soil type, harvesting, insect damage, etc. A trial location with a large LSD (least significant difference) and large CV (coefficient of variation) indicates a higher degree of variability at the trial location. A CV of 15% or less is generally considered acceptable and means the data are dependable. Trials with a small LSD indicate more consistency within the trial and higher likelihood of identifying differences among varieties. Two varieties that have a difference in yield or other parameter that is smaller than the LSD are not significantly different than each other for that parameter. Likewise, a variety that is within the range of the LSD is not significantly different than the highest variety in the trials. Non-significance is represented as “NS” and indicates no differences among the varieties within the data column at a 5% significance level.

## ***First 40 Days – Fruiting to Finish***

### **The Most Critical Period in Cotton Production**

#### **Expert Recommendations of Best Management practices for an Efficient, Cost Effective Cotton Production System**

##### **Variety Selection**

Cultivar selection is the most important decision made in the production enterprise. This decision has a lasting effect on the crop's early-season vigor and on over all plant health and uniformity during the First 40 Days. The crop's ultimate yield and fiber quality potential at harvest begin with variety selection and seed quality.

- ❖ Consider planting disease tolerant varieties, or those that have at lease some resistance, where disease is a problem.

##### **Choose Varieties with Genetic Potential for Higher Yield and Excellent Fiber Quality**

Yield remains the ultimate measure of the crop, although the ever-increasing demand for higher fiber quality makes this factor a close second in priority. With more than 70% of the U.S. crop exported, fiber quality will become the single most important factor for U.S. cotton in the foreseeable future. International mill standards and specifications are higher than domestic mills.

- ❖ Long staple length - >35 (>1.08 inches)
- ❖ High strength - 28 to 29
- ❖ Premium micronaire - 3.8 to 4.8
- ❖ High uniformity Index - 82
- ❖ Smooth leaf with plant confirmation suitable for efficient harvest - 21/31 Grades 2-3 leaf

##### **Plant Several Varieties: Consider Specific Traits and Crop Maturity after Yield and Quality**

Consider planting 3 to 4 varieties to determine which cultivars and trait combinations perform best on your farms. Multiple varieties also minimizes the risk of planting the entire farm to a potentially poor performing variety or using traits that do not add value to the individual cropping system.

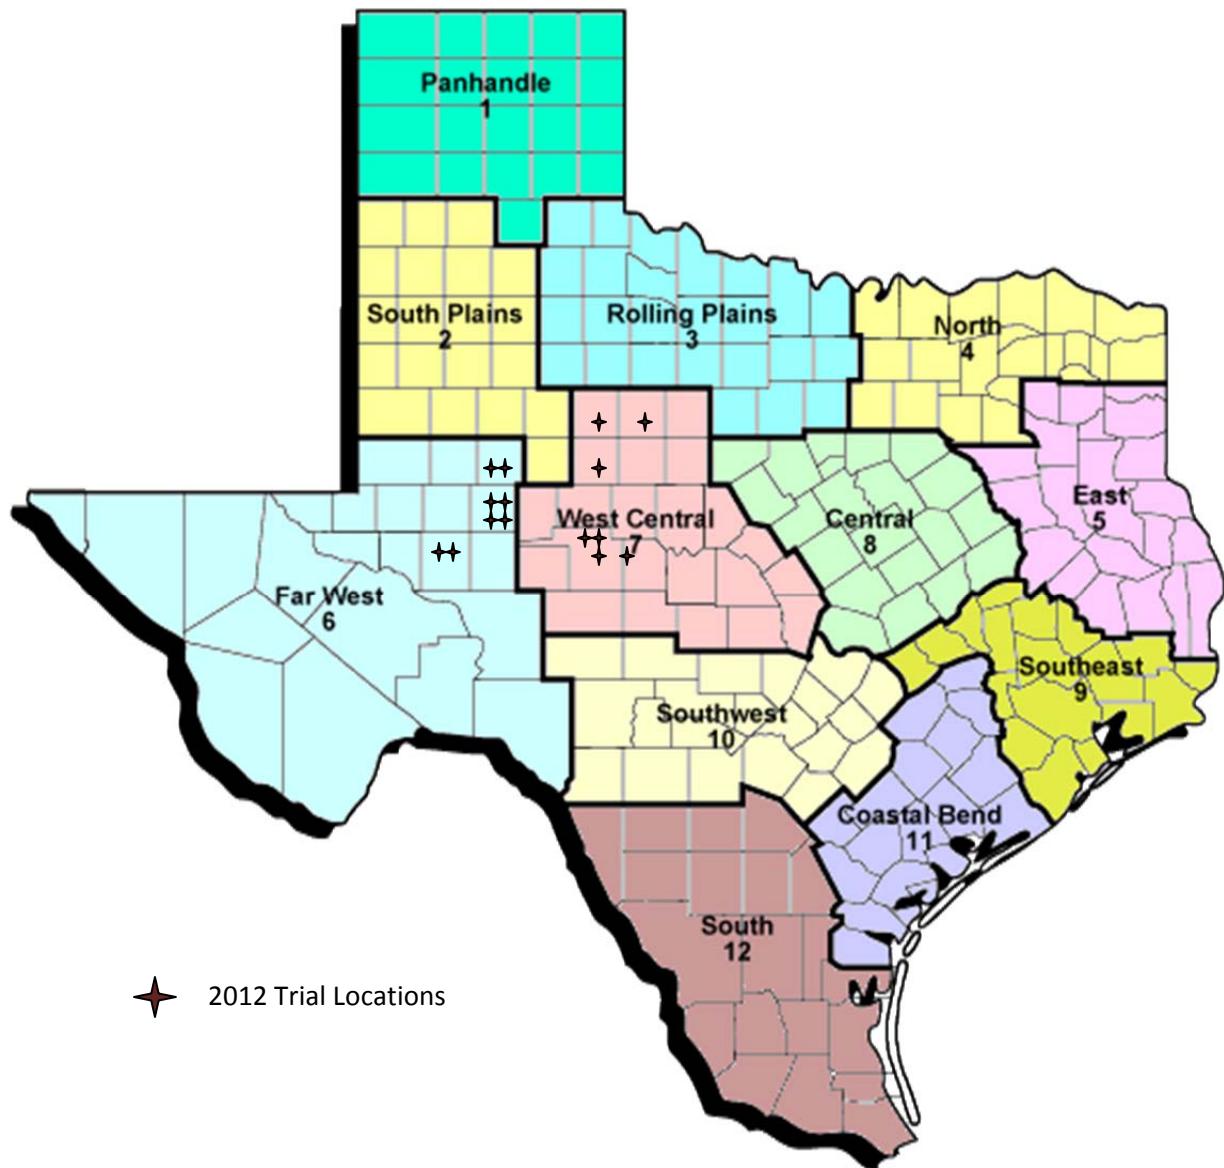

- ❖ Always evaluate more than one year of variety data prior to planting large acreage to a new cultivar.

##### **Select the Highest Quality Seed for Planting**

High quality seed is critical to early success and the crop's ultimate performance. Rapid germination and emergence is best because it narrows the window for seedling disease and minimizes pest impact. In addition to the standard warm germination test, a cool germination test is recommended. Cool/Warm Vigor Index of 160 is best (e.g. 90 warm germ + 70 cool germ - 160)

Early planting into cool soils requires the best vigor index available in the variety you are planting

- ❖ CWVI >160 = Excellent
- ❖ CWVI 140-159 = Good
- ❖ CWVI 120-139 = Fair
- ❖ CWVI <120 = Poor

<sup>1</sup> Values for varieties shaded in gray or marked with (\*) are not significantly different than the highest treatment in the column

<sup>2</sup> Fiber quality analysis conducted by sending a single ginned fiber subsample for HVI at the Fiber and biopolymer Research Institute, Texas Tech University, Lubbock, TX.

<sup>3</sup> color and leaf grade based on a single sample.

<sup>4</sup> Gross Seed Return based on \$300/ton

<sup>5</sup> The statistical analysis indicates a general overview of the uniformity or variability of the test conditions, such as soil type, cultural practices, insect damage, etc. Trial locations with large least significant differences (LSD's) and CVs indicate a higher degree of variability. The smaller the LSD, the more precise are the test results and higher likelihood of identifying differences among varieties. Differences between varieties that are greater than the LSD indicate a significant difference between them for the measurement in a column. n.s. indicates no statistical difference among the treatments for that particular measurement/column.

Acknowledgements of assistance from Michael Block, Producer; Rick Minzenmayer, Pam Halfmann, Dr. Chris Sansone, Justin Mullens, Travis Holle and the sponsoring companies.

<sup>1</sup> Values for varieties shaded in yellow or marked by an (a) are not significantly different than the highest treatment in the column and values shaded in orange are above average for that parameter/column

References to commercial products or trade names is made with the understanding that no discrimination is intended and no endorsement by Texas A&M AgriLife Extension Service is implied.

Mention of a trademark or a proprietary product does not constitute an endorsement of the product by Texas A&M AgriLife Extension Service and does not imply its approval to the exclusion

of other products that also may be suitable. Abbreviations include: All-Tex (ATX), Bollguard II (B2), Croplan Genetics (CG), DeltaPine (DP), FiberMax (FM), Glytol (G), Liberty Link (L)

NexGen (NG), PhytoGen (PHY), Poncho Votivo seed treatment (PV), Roundup Flex (F or RF), Stoneville (ST), and Widestrike (W).

<sup>2</sup> Fiber quality analysis conducted with a minimum of two ginned fiber subsamples by HVI at the Fiber and biopolymer Research Institute, Texas Tech University, Lubbock, TX

<sup>3</sup> color and leaf grade based on a minimum of two samples. Values followed by an (\*) indicate a difference between the samples.

<sup>4</sup> CCC loan value based on cotton stored at Lubbock, TX. Base \$51.70

<sup>5</sup> Gross Seed Return based on \$300/ton

<sup>6</sup> The statistical analysis indicates a general overview of the uniformity or variability of the test conditions, such as soil type, cultural practices, insect damage, etc. Trial locations with large least significant differences (LSD's) and CVs indicate a higher degree of variability. The smaller the LSD, the more precise are the test results and higher likelihood of identifying differences among varieties

Differences between varieties that are greater than the LSD indicate a significant difference between them for the measurement in a column.

n.s. indicates no statistical difference among the treatments for that particular measurement/column

References to commercial products or trade names is made with the understanding that no discrimination is intended and no endorsement by Texas A&M AgriLife Extension Service is implied.

Mention of a trademark or a proprietary product does not constitute an endorsement of the product by Texas A&M AgriLife Extension Service and does not imply its approval to the exclusion

of other products that also may be suitable. Abbreviations include: All-Tex (ATX), Bollguard II (B2), Croplan Genetics (CG), DeltaPine (DP), FiberMax (FM), Glytol (G), Liberty Link (L)

NexGen (NG), PhytoGen (PHY), Poncho Votivo seed treatment (PV), Roundup Flex (F or RF), Stoneville (ST), and Widestrike (W).

2 Fiber quality analysis conducted with a minimum of two ginned fiber subsamples by HVI at the Fiber and biopolymer Research Institute, Texas Tech University, Lubbock, TX

3 color and leaf grade based on a minimum of two samples. Values followed by an (\*) indicate a difference between the samples.

4 CCC loan value based on cotton stored at Lubbock, TX. Base \$51.70

5 Gross Seed Return based on \$300/ton

6 The statistical analysis indicates a general overview of the uniformity or variability of the test conditions, such as soil type, cultural practices, insect damage, etc. Trial locations with

large least significant differences (LSD's) and CVs indicate a higher degree of variability. The smaller the LSD, the more precise are the test results and higher likelihood of identifying differences among varieties

Differences between varieties that are greater than the LSD indicate a significant difference between them for the measurement in a column.

n.s. indicates no statistical difference among the treatments for that particular measurement/column
